NATURAL RESOURCE SCIENCE AND MANAGEMENT IN THE WEST

Issue 11

ROAD ECOLOGY
Traffic Noise
Wildlife Deaths
Road Design
Exploring and Connecting

A publication of the William D. Ruckelshaus Institute at the University of Wyoming’s Haub School of Environment and Natural Resources
“For many Americans, the open road best captures the essential character of the West—unfinished, open-ended, a marriage of the human psyche with the earth, sky, and highway,” writes geographer William Wyckoff.

We’ve all been there, driving fast on a ribbon of asphalt, watching a distant thunderhead boil up, counting raptors on fenceposts, creating a long geologic uplift only to have the last FM station flicker to static. These roads of the West mean everything to us, linking our scattered towns and cities with the most remote ranches and energy fields, carrying goods and newspapers, food and medicine, letters and visitors. We need our roads. We take our roads for granted, forgetting how extensively they shape our existence. And we curse our roads when they are clogged with construction or sheathed in deadly ice.

Like any human-built infrastructure, roads also change the places they cross. In the last few decades, researchers and ecologists have begun to look carefully at the ways roads disrupt natural systems. We open this issue with an introduction to the Western Transportation Institute, a research unit based at Montana State University in Bozeman, to illustrate the cutting-edge ways road ecologists are scrutinizing roadway impacts and devising solutions to mitigate the damages they cause (page 2).

Some of the damage is apparent, marked with legions of bloody wild animal carcasses, small and large, smacked by speeding vehicles (pages 4, 6, 10, and 12). Other influences are more subtle, such as the way roads alter wildlife behavior even when the animals aren’t struck (pages 12, 14, 16). The more we learn, the better we can do to blunt the harsh disruptions roads bring to our wild lands. For example, ecological datasets can inform ways to divert new roads around fragile natural areas (page 30). One simple way to mitigate road damage is to reduce speed limits, especially at certain times of day or year when animals are most susceptible (pages 12 and 45). Researchers and highway managers are even designing crossing structures to safely ferry wild animals over or under roadways (page 26). In the case of massive Interstate 80, which acts like a wall across hundreds of miles of big game habitat in southern Wyoming, new wildlife crossing structures might begin to stitch a broken landscape back together (page 16). Of course, as one researcher in this issue puts it, “Not building new roads is the number one conservation action” (page 15).

This exploration into the field of road ecology took us in some less-expected directions, too. You’ll find an essay about a highway engineer and his care in designing roads through the desert he loved (page 28). And you’ll join an adventurer who explores abandoned mining roads by mountain bike and discovers something other than the ruined industrial site she expected (page 43). Roads are part of our human experience on the landscapes where we dwell. Even as they disrupt wild places, they also mediate our connections to the land, indeed linking our psyches to the earth and sky.

UPSTREAM
45 Intersecting Roads
The need to value and safeguard wildlife movements
Perspective from Corinna Riginos
When I drove across Wyoming’s stretch of Interstate 80 to film a wildlife documentary in fall 2019, I saw animals confronting the highway barrier again and again. At Dana Ridge in southeast Wyoming, I saw pronghorn making heavily tracked trails through snow. Constrained by fences and traffic, their hoofprints paralleled the interstate just outside the right-of-way fences for many miles. Near Sinclair, 18 miles further west, I saw carcasses where pronghorn

Interstate 80 severed wildlife habitats 50 years ago. Can we reconnect them?
had somehow made it through the interstate fence, only to collide with the traffic.

West of Little America, 150 miles farther on, I met Wyoming Game and Fish Department biologist supervisor Mark Zornes, who showed me the spot where one semi truck killed 25 pronghorn in 2017. The animals were trying to move south to better winter range near Flaming Gorge but got trapped and run over on a foggy morning. At the Leroy exit near the Utah border, I saw mule deer tracks going through an underpass that the Wyoming Department of Transportation (WYDOT) had retrofitted for wildlife.

Thanks to GPS research, I can now fit all these wildlife anecdotes into the big picture of southern Wyoming’s landscape, where 400 miles of I-80 chop up habitat and obstruct movements that animals depend on for their survival.

When the last major segment of I-80 in Wyoming officially opened for traffic more than fifty years ago on October 3, 1970, it bisected movement corridors for tens of thousands of big game animals. After eons of free-roaming life for these migratory herds, we’d plunked down a railroad, fences, and a superhighway through the middle of their home turf.

For wildlife, I-80 is something like a Great Wall of China across the desert basins of southern Wyoming. The traffic volume of 5,000 to 13,000 vehicles per day makes the interstate virtually impenetrable to wildlife. On top of that, sections of the interstate are lined with eight-foot-tall exclusion fences to prevent wildlife-vehicle collisions. The barrier bisects many otherwise functional migration corridors, cutting off access to vast seasonal ranges and potential habitat, and limiting animals’ options to survive winter storms and summer droughts.

Worldwide, human development and roads are pressing in and slicing across the habitats of migratory ungulates (hooved mammals). These ecological changes ultimately threaten migratory behavior and the survival of entire populations. One doesn’t have to look far, just to the Front Range of Colorado or the Wasatch Front in Utah, to see just how completely migration can be curtailed. These urbanized Rocky Mountain landscapes stand in contrast to Wyoming, where the naive first-time driver on I-80 may tell you there is nothing out there. Look closer though, and all that openness is punctuated with towns, the Union Pacific railroad, livestock fences, irrigated fields, subdivided private property, oil and gas wells, coal and trona mines, power plants, transmission lines, windmills, and solar farms. It’s a working landscape, busier than it has ever been.

And yet, moving through it all is still-abundant wildlife—likely more than you will see anywhere on I-80 from New York to San Francisco. Amid the islands of development in southern Wyoming, animals roam over wide swaths of relatively intact habitat. Places like the Great Divide Basin, which I-80 crosses in south-central Wyoming, are not so badly degraded that they can’t be returned to greater function.

In the last 50 years, scientists tracking wildlife have moved from radio collars to sophisticated GPS mapping, revealing that the most severe fragmentation is due to the single, solvable barrier of I-80. Wyoming biologists and engineers generally agree that the time has come to address this problem and find new solutions for connectivity on I-80. The revolution in wildlife movement science is creating a vision for a reconnected landscape, one that bucks the global trend of habitat fragmentation, and restores free wildlife movement on a grand scale.

CURTAILED MOVEMENT

Signs of trouble for wildlife were already evident. As early as 1965, while construction was still ongoing, Wyoming Game and Fish Department biologist Bill Hepworth expressed concerns that I-80 and Interstate 25 would hamper pronghorn movements, because they generally do not jump over right-of-way fences like deer or elk. ‘Curtailed movement of some herds appears critical,’ Hepworth wrote. By 1967, biologist Darwin Creek had assessed that I-80 traffic and fences had virtually stopped north and south movements of pronghorn in sections where the road was completed.

The new I-80 barrier combined with grazing allotment fences to create fatal consequences for migratory animals. In October 1971, a devastating blizzard roared across the interstate west of Rawlins, dropping 18 inches of snow. Huge numbers of pronghorn looking for areas with less snow succumbed to exhaustion at woven-wire fences and along I-80. Many were scavenged by coyotes, or completely buried by snow, such that biologists Phil Riddle and Chuck Oakley couldn’t make an accurate survey of the losses until the spring. Later aerial counts estimated that 3,111 pronghorn, or
more than 60 percent of the Chain of Lakes population near Rawlins, had perished. While these deaths didn’t all happen along the interstate fence, they indicated a larger problem of lost connectivity for southern Wyoming pronghorn that rely on movement. Quite simply, when animals could no longer move freely to escape harsh conditions, they died.

At the request of the Wyoming Game and Fish Department, WYDOT built the Elk Mountain to Walcott Junction segment of I-80 with a number of underpasses for deer. On the western slope of Dana Ridge, workers built three box culverts and two machinery underpasses, but deer were very reluctant to use them. By 1976, six years after opening to traffic, some 725 animals had been killed on the 80 miles between Laramie and Walcott. The tally included 561 mule deer, 153 pronghorn, and 10 elk. The situation was bad enough that the Wyoming Game and Fish Department and WYDOT used funding from the Federal Highway Administration to solicit a study on how to reduce the mortalities and risks to motorists.

Lorin Ward at the US Forest Service Rocky Mountain Forest and Range Experiment Station led the research. In the winter of 1977-78, Ward tasked biologist Hank Henry with living in a trailer on the side of I-80 at the summit of Dana Ridge. It’s a spot where about 900 mule deer migrated through every spring and fall, some going as far as 50 miles from the Snowy Range to the Haystack Mountains along the Platte River.

Henry was faced with the impossible task of trying to keep deer from doing an end-run around an eight-foot-tall exclusion fence designed to keep animals from getting hit on the highway. It was a long, lonely season, and sometimes he’d use roman candle firecrackers to scare deer away from the road. But the animals’ urge to migrate was too strong. Some mornings he’d wake up to find holes in the fence where deer had squeezed through. Other times the pavement was covered with a mix of glare ice and blood where deer had met their end.

Ward and his team eventually settled on extending the exclusion fencing to better keep animals off the highway, and direct them toward the underpasses. Within a few seasons, deer encouraged by fenching and apples as bait had learned to use the crossing structures, allowing nearly 1,000 safe deer crossings per year, and a 90 percent reduction in mortalities at that location.

While pronghorn could not access the underpasses due to fences, and elk corridors were located elsewhere, about 400 deer still use these structures today. This was a major success story for deer, one that was repeated with underpasses at the “Sisters” area west of Fort Bridger. Yet, these were some of only a few wildlife crossing structures built in the state, and they only helped one species in a few specific areas.

Ward offered no suggested solution for pronghorn or elk crossings on I-80. “Since antelope are reluctant to jump fences and use underpasses, I-80 is a barrier and the herds are managed accordingly,” Ward wrote. “Since elk are large, they present a greater hazard to motorists, and should be discouraged from crossing highways by proper fencing and road location.”

Reading this statement today, it seems that for Ward the primary motivations behind the Dana Ridge crossing structures were preventing wildlife mortalities and reducing risks to motorists. If pronghorn and elk didn’t cross the interstate, and deer could cross safely using underpasses, then the safety issue was largely resolved for WYDOT and the Federal Highway Administration.

On the flip side, Ward seemed to imply that the wildlife connectivity problem was one for wildlife managers and biologists, who would have to accept the I-80 barrier as they pursued more wildlife tracking research. It remained difficult to assess the full scale of movements for the different species across 400 miles of highway, and how they had been curtailed. Biologists had only limited technology to understand or address the problem and wouldn’t get a more complete picture for several decades.

Biologists improvised tracking methods in creative ways, hoping to learn movement patterns and locations of summer and winter ranges that were affected by the interstate. Lorin Ward’s team placed blaze orange collars on three deer in hopes of spotting them later in a different spot, but the effort only defined the winter range for a single animal.

Hepworth tried to mark pronghorn with ear tags, or with Nyanzol D black dye applied from an
aircraft. He hoped for the development of a long-lasting fluorescent green or red dye that would be more visible. In lieu of that, Hepworth was sometimes able to document large movements by spotting a pronghorn buck with atypical horns in two distant places, but he wanted better methods. “A satisfactory means of marking large numbers of animals, preferably on an individual group or individual animal basis, is a must to aid in the study of migration and movement,” he wrote in 1965.

Connectivity was also on his mind. “The effects of various barriers to antelope movement, particularly barriers to the critical movement to winter or summer range and water, are of primary concern at present…. Much work needs to be done to find fences and/or devices to allow movement,” Hepworth wrote, but, he lamented, “investigations into the basic ecology of antelope are still lacking.”

Wildlife managers knew there was more to the story, but they would need better tools to fill in the picture of how much I-80 was altering wildlife movements. It would take half a century for the technology to catch up and make answers to these questions come into focus.

THE GPS REVOLUTION

When the long-desired animal-tracking revolution arrived, it brought many surprises about where migratory ungulates go, and how they interact with barriers.

On November 12, 2013, biologist Adele Reinking’s team collared pronghorn Yellow-13 on the west side of US 789, 11 miles south of I-80. When Reinking later mapped the data on her computer, the thousands of GPS fixes of Yellow-13’s movement were all arranged into a mysteriously precise rectangle with an area of less than six square miles.

Zooming in, Reinking realized that the day after the pronghorn was collared, it had made its way into a grazing enclosure in a natural gas extraction area. Yellow-13 remained inside that same fenced area for 16 months, until April 7, 2015, at which point she escaped confinement, only to die of unknown causes at the end of September.

“So, most of the last two years of her life were spent in a very small, highly-developed area that she was likely not able to leave because of fencing,” Reinking said. For a species that can run 50 miles per hour and range over hundreds of miles, one can only imagine the feeling of being trapped in a wire cage under open Wyoming skies.

The seeds of the GPS revolution had been planted decades earlier, at about the same time I-80 was completed across Wyoming. NASA first experimented with a satellite tracking collar on a Jackson Hole elk named Monique early in 1970. The technology was cumbersome and prone to malfunction, but it was the start of Wyoming’s role in an animal tracking revolution.

Later, very high frequency (VHF) radio telemetry collars became the standard wildlife tracking technology used by biologists, though they required laborious triangulation fieldwork and often revealed just a handful of data points. Even so, radio tracking yielded dense information about winter ranges where animals spent a lot of time, and informed a major push to conserve those ranges for big game herds during the 1980s and ’90s.

By the early 2000s, satellite monitoring of wildlife became much more accessible to biologists due to the development of GPS collars with a year or more of battery life. The initial iteration was “store on board” GPS collars that weighed very little and held the satellite antenna and storage chip in compact boxes worn around an animal’s neck.

These devices communicated with satellites to pinpoint locations at programmed intervals and kept the data on the internal chip. After a year or two, a release mechanism activated and dropped the collar to the ground. The biologist then retrieved the collar from the field and downloaded the data.

Despite the inconvenient delay in accessing data, store-on-board collars represented a major technological leap forward, and they ignited a rapid advancement of migration science in Wyoming. The patchwork of radio telemetry data gave way to a clear picture showing how animals move 24 hours a day, through all four seasons and multiple years.

Fast forward to 2020, and GPS collars have advanced further to real-time collars linked to remote computers via the Iridium satellite network. Such devices can log locations every few hours for two to
Trappers Point
WYDOT completed the world’s first overpass for pronghorn in 2012. Migratory pronghorn immediately began using the structure, making thousands of safe crossings each year. Together with the Borciff Hill overpass, six underpasses and fencing, the project reduced mule deer mortality along this 12-mile stretch of highway by 80 percent, and took pronghorn mortalities to zero. In 2018, collared pronghorn 700031A used this overpass and then migrated all the way to I-80.

Dry Piney
To address the Wyoming Wildlife Roadways Initiative’s number three priority statewide, WYDOT, Wyoming Game and Fish Department, and partners have pooled more than $19 million to build fences and underpasses. The project will reduce traffic mortalities for mule deer, pronghorn, and moose along 19 miles of US 189.

Nugget Canyon
This landmark wildlife crossing project built in summer 2008 showed the effectiveness of underpasses and fencing in reducing mule deer mortalities. Deer made nearly 6,600 crossings from Oct. 1 to Dec. 22, 2009, along with elk and moose.

Wyoming Highway 372
Barriers such as a highway, railroad, solar farm, and mining constrict pronghorn movements. Biologists suspect that pronghorn would benefit from being able to cross south of the interstate.

Granger Junction, Exit 66
In the winter of 2017, a trucker driving eastbound on I-80 killed 25 pronghorn that entered the right-of-way. The animals were likely trying to migrate south toward Flaming Gorge where there is less snow.

The Three Sisters
Near prominent ridges known as the Three Sisters, fences guide deer herds through large box tunnels built during initial construction of I-80. Tracks show deer are also crossing the interstate through a six-foot-tall culvert. Here, the author found bones from a fawn that died in a woven-wire gate, suggesting further fence improvements may help wildlife in this area.
ECONNECTING A VAST LANDSCAPE

GPS tracking collar data reveals how Interstate-80 disrupts migratory big game movements in Wyoming. New wildlife crossing structures could reconnect habitats that have been severed for 50 years.

Point of Rocks
Mule deer run up against I-80 after migrating 150 miles from the Hoback Basin to the Red Desert, and crossing two highways and more than 100 fences. Biologists wonder how far these deer might continue if I-80 didn’t stop them.

Baggs
In summer 2009, WYDOT and Wyoming Game and Fish Department installed a wildlife underpass on US 789 six miles north of Baggs. Cameras recorded an impressive 5,100 crossings by migrating mule deer from Sept. 1 through Dec. 21, 2010. Elk also use this structure.

Table Rock
GPS data shows pronghorn obstructed on both sides of the interstate. A wildlife crossing structure here could enable long-distance animal movements. Biologist Ben Redd tracked a Table Rock pronghorn 100 miles south to near Sunbeam, Colorado across the state line.

Wamsutter
Few pronghorn have ever been observed to cross I-80. Biologist Adele Reinken colored pronghorn Orange 25 some 50 miles south of the interstate near Baggs. Later, she spotted the same animal on the north side at Love’s truck stop in Wamsutter, though the collar battery died and the data was never retrieved.

Dana Ridge
When the interstate was completed in 1976, this migration thoroughfare became a hotspot for collisions with mule deer. In the late 1970s, workers added fences to funnel deer through a machinery underpass and tunnels. Deer, such as the GPS-collared animal shown here, still cross I-80 using these structures, but elk and pronghorn do not.

Intestate 80
This highway is a known barrier to mule deer and pronghorn along the Laramie Range, Casper Mountain, and the Bighorn Mountains. Research and mitigation efforts are underway, especially between Kaycee and Buffalo beyond the north edge of this map.

Halleck Ridge
This is the Wyoming Wildlife Roadways Initiative’s highest-priority location on I-80. In 2020, WYDOT and Wyoming Game and Fish Department began assessing improvements to existing underpasses and fences, along with new crossing structure options.

Southeast Wyoming
Research in the 1970s tracked deer and elk responses to the interstate from the Laramie Range to Dana Ridge. One study showed that elk heart rates increased when they approached I-80. Only minimal recent wildlife movement data is available from the Colorado and Nebraska borders to west of Laramie.

three years, feeding a constant stream of information to researchers in the office.

Biologists coupled this wealth of data with computerized statistical methods to open up new analytical avenues and questions. In recent years, biologists have produced landmark studies on the outsized nutritional contributions of stopover habitats and the migration corridors in southern Wyoming. And that movement barrier reduces the options that animals in these populations have…

—Hall Sawyer

animals don’t want to cross.

When I placed trail cameras at Dana River and the Platte River bridge, the videos documented pronghorn eyewash underpasses that were fenced off, presumably to manage livestock. The clips seem to show pronghorns getting through the barrier and wire and beyond to the opening underneath the highway, as if wanting to cross. Seeing no way through, they walk away instead.

The seldom few that cross the interstate anyway do so in less than ideal conditions, like busy road interchanges or by fighting their way through difficult fences. "I find it exciting that pronghorn are using locations that are not designed with them in mind," Robb said. It speaks to the possibility that pronghorn would readily use crossings that are designed for them. The evidence suggests that if offered a little more help their wild instincts would readily reconnect this fragmented landscape, moving vast habitats and benefitting movement and survival.

LOOKING FORWARD

Back in 1976, Loren Wendt’s report on deer along I-80 ended with this recommendation: “Cooperation between highway designers and wildlife managers can effectively reduce the number of deer–vehicle collisions.”

Today, Wyoming Game and Fish Department and WYDOT have teamed up on the Wyoming Wildlife Roadways Initiative, a collaborative effort between agencies. The coordination is empowered by an enormous amount of data that can help to identify potential crossing designs and locations, reconnecting suitable habitat both on I-80 and across the state.

The initiative evolved out of WYDOT and the Wyoming Game and Fish Department’s Wildlife and Roadways Summit held in Pinedale in April 2017. The conference set in motion efforts to identify the top wildlife-roadway “opportunity zones.” These represent the most pressing areas for improving wildlife passage across Wyoming’s highways, using criteria like migration corridor, wildlife vehicle collisions. Of the 43 projects identified, eight are along I-80.

These are a tough issue using current technology and mapping to share wildlife-roadway information with the public through the Wyoming Wildlife Roadways Initiative website. All the data is helping to design solutions that range from simple and inexpensive, to complete engineering feats that cost in the millions or tens of millions of dollars. Starting on the simple end, improving fences to benefit wildlife is the easiest to implement. The most common actions are removing fences or changing woven-wire fences to wildlife-friendly designs. Such actions help improve connectivity on habitat adjacent to I-80 and provide an ecological benefit even without crossing structures for I-80.
“Someone asked me what’s the best way to invest our money, and I think fence modifications,” Reinking said. Significant gains could be made for Red Desert pronghorn by improving fences in ranges north and south of the highway, she thinks. “I would prioritize that over making it easier to cross I-80. I think the fencing is a much easier, faster, lower investment fix, than an overpass, which we know for pronghorn is almost required.”

Wildlife movement data can help target these fence retrofits efforts. Rawlins Bureau of Land Management (BLM) Office biologist Mary Read consulted with Reinking to identify fences that were blocking pronghorn movement, working off an initial $50,000 budget. In 2018 and 2019, the BLM and partners funded more than $250,000 in fencing work, addressing almost 22 miles of range fence in 55 locations. While most of these projects are not immediately adjacent to I-80, they reduce the movement barriers for herds that are also dealing with the highway.

“When Mary Read came to us with $50,000,” Reinking said, “that is not enough for an overpass, but it can fix a hell of a lot of fences.”

The next step up for restoring connectivity is modifying existing infrastructure like underpasses and bridges to enable or enhance wildlife passage. There are more than 200 existing underpasses between Cheyenne and Evanston for livestock and machinery, and many have the potential to be retrofitted to enhance wildlife movement. Hall Sawyer and Bill Rudd compiled a 2006 report documenting some of these existing structures along I-80.

Ben Robb has placed dozens of camera traps at existing machinery underpasses and bridges to monitor any wildlife usage. “Spoiler alert: We are finding that underpasses that have a fence on them are not used by pronghorn,” Robb said. One way to increase use of these structures could be to retrofit woven-wire fences and use smooth bottom wires that are high enough for pronghorn to scoot under. Such retrofit projects could build on the knowledge acquired by 1970s crossing projects at Dana Ridge and the Sisters, and more recent underpasses built at Trappers Point, Nugget Canyon, and Baggs (see map).

Then there is the option of creating new crossing structures: underpasses or overpasses. There is wide agreement that the best solution for pronghorn to cross the interstate is a wildlife overpass. In Wyoming, that impression is largely shaped by the success of the Trappers Point overpass over the two-lane US 191 near Pinedale, Wyoming. A 2016 Wildlife Society Bulletin paper by Hall Sawyer, Patrick Rodgers, and WYDOT’s Thomas Hart found that pronghorn vastly preferred to use overpasses compared to adjacent underpasses.

Migrating pronghorn began using the Trappers Point overpass immediately after it was completed in 2012. During the next three years, the overall project of 12 miles of fencing, six underpasses, and two overpasses eliminated pronghorn-vehicle mortalities, and reduced mule deer road mortalities by 79 percent. Mule deer made more than 40,000 crossings, and pronghorn made more than 19,000 crossings. Many of these were back-and-forth movements that allowed animals the flexibility to intermingle during the autumn rut and respond to changing environmental conditions on winter ranges.

These impressive numbers for a 12-mile project on a two-lane highway only begin to suggest the magnitude of connectivity that could result if crossing structures were built at key places along Wyoming’s 400 miles of I-80. While Wyoming has no I-80 wildlife overpasses so far, in Washington, Nevada, and Utah there are several that bridge four-lane interstates, proving the concept is feasible. The track record for these structures goes back to 1975, when Utah built the first wildlife overpass in the United States across Interstate 15 near the town of Beaver.

In the absence of an overpass, anecdotes show pronghorn use interstate underpasses under certain conditions. UW biologist Jeff Beck once saw a group of about 15 pronghorn crossing under the Wolcott Junction interchange of I-80, heading south toward Saratoga. In September 2019, transmission line inspector Waylon Dyess of Rock Springs saw about 50 pronghorn cross under the interstate from south to north at the Tipton interchange, on the west edge of the Great Divide Basin. In the winter of 2019-20, Phil Damm, Fort Bridger biologist for Wyoming Game and Fish Department, saw tracks that substantiated reports of hundreds of pronghorn crossing east to west at the US 789 underpass north of Baggs.

“I have had professionals outside of Wyoming tell me that pronghorn don’t use underpasses, end of story,” Robb said.
"And I hope [my research] could change the story, that actually, the underpasses may not be ideal, but they will use it in the absence of other options."

Wyoming biologists generally agree underpasses could also be a good solution for mule deer or elk when placed in the right locations. It’s possible that such structures, combined with exclusion fencing, could help prevent deadly elk collisions that have occurred near Little America, Jim Bridger Power Plant, and Rawlins in recent years.

There are a number of hurdles in the way of building new crossing structures across I-80. These range from design challenges due to drifting snow conditions and proximity of the railroad, to land ownership issues that would require coordination between public agencies and private interests. However, the biggest challenges may lie in current policy priorities and limited funding streams.

When WYDOT and the Wyoming Game and Fish Department prioritize wildlife-highway projects, restoring habitat and migration movement is only one of several considerations. Projects that are most likely to improve driver safety tend to rise to the top in terms of urgency, and on the local level some two-lane highways are greater hotspots for wildlife-vehicle collisions. Overpasses on I-80 may benefit wildlife immensely, but they might not do a lot for driver safety.

There is also the sheer cost. Along I-80 at the Pequop Range and Silver Zone Pass in Nevada, a series of three wildlife overpasses, numerous underpasses, and fencing required an outlay of about $20 million. Depending on the location, a project could cost more in Wyoming if a separate overpass were required to go over an adjacent access road, not to mention the Union Pacific railroad.

"We don’t want to just pour [animals] out across the interstate and right onto the railroad," said Scott Gamo, environmental services manager for WYDOT. Despite WYDOT’s buy-in on the importance of wildlife connectivity, sufficient money for that purpose alone won’t come from the agency, so the state would need to find other funding sources. A federal appropriation would be one solution, and there are potential ways to raise funds through grants. For the Dry Piney wildlife crossing project over a two-lane highway near LaBarge, WYDOT secured a $14.5 million grant and additional matches from Wyoming Game and Fish Department and other partners for a total of $18.5 million. Construction of up to eight wildlife underpasses and associated fencing will begin in 2022.

"We [at WYDOT] want to do our part to certainly minimize if not eliminate mortalities for wildlife if we can," Gamo said. "If we can do that to benefit people and wildlife, that is obviously a win-win…. A bigger push now, than it was in the past, is looking at the habitat. It’s moving that way for WYDOT."

The Wyoming Game and Fish Department’s statewide wildlife-roadway work with WYDOT continues long-standing habitat and research efforts that Hepworth and others undertook along I-80 in the 1960s and ‘70s. "It’s exciting to see how evolving technology, like GPS collars, has allowed us to better..."
understand wildlife movement in relation to I-80,” said Wyoming Game and Fish Department Deputy Director Angi Bruce. “Game and Fish is committed to working with WYDOT and other partners to rely on this expanding data to improve wildlife connectivity and public safety on I-80 and throughout the state.”

Finally, engineers and biologists have to decide where to site crossing structures to best restore movement across I-80, when corridors have been severed for 50 years. To analyze the options, Ben Robb completed an analysis of high-quality pronghorn summer range and winter range, and then modeled ways to “connect the dots” across I-80. He successfully defended his thesis on this research in fall 2020.

“This will give us valuable information of feasible options that can let pronghorn continue to freely move, and have the right to roam in Wyoming,” Robb said.

Any future gains for wildlife connectivity, both on I-80 and elsewhere, will likely be built on a foundation of public interest, collaborations, and creative funding. There are murmurs that a federal infrastructure bill could include funds for wildlife projects, but if experience is any indicator, Wyoming’s own initiative will be the deciding factor.

As of this writing, work has begun to enhance wildlife connectivity in the Halleck Ridge area of I-80, just east of Dana Ridge. This is the Wyoming Wildlife Roadways Initiative’s number two priority wildlife-roadway project for all of Wyoming. WYDOT contracted with Western EcoSystems Technology (WEST) to analyze GPS data and create a list of potential enhancements. The project is looking at ways to upgrade fencing or enhance culverts or underpasses to help animals cross. WEST has also contracted with an engineering firm to examine potential locations for an overpass and do initial drawings. The planning doesn’t mean an overpass will be built, but that it could be one of the options on the table for WYDOT’s consideration. Fence crews are already working in the area.

If a large-scale wildlife overpass or underpass project does come to fruition at Halleck Ridge, that could lay the groundwork for future efforts along the length of the interstate. Research suggests intriguing possibilities, most of which match with priorities set by WYDOT and Wyoming Game and Fish Department.

Crossing structures on I-80 could enable mule deer and pronghorn corridors that start as far away as Jackson Hole or Yellowstone to continue across I-80, and even into Colorado, connecting the great wildlife winter ranges of the two states. In particular, biologists wonder how much father mule deer on the 150-mile-long Red Desert to Hoback mule deer corridor might go if I-80 didn’t block them at the southern end.

Near Fort Steele, Creston Junction, Wamsutter, or Table Rock, crossing structures could enhance pronghorn winter range movements. If a crossing structure were built in those areas, there is a chance that pronghorn north of the interstate would find a way to move a long distance south. In 2019, Ben Robb tracked a pronghorn from the Table Rock area near Sunbeam, Colorado along the Yampa River, a distance of 100 miles.

Further west of Green River, I-80 wildlife crossings could help relieve connectivity issues along WY 372 created by a solar farm. “It almost looks like that place needs a relief valve because animals get trapped in there,” Gamo said. “If the animals could have an outlet to the south there, that may alleviate some of those issues.” An ongoing study by Western EcoSystems Technology will help pin down pronghorn movement patterns in this region and evaluate whether fence removals and a 50-meter movement corridor between the solar farm and WY 372 could help pronghorn. A separate study is looking at Uinta Range mule deer movements from The Sisters to Kemmerer.

Since that day in October 1970 when I-80 was completed across Wyoming, 50 years of research has clearly laid out the wildlife problems, and the options to fix this barrier once and for all. Any connectivity projects could stand to make a large difference for wildlife along I-80, effectively multiplying the amount of habitat available.

“A lot of places just don’t have that open swath of sagebrush habitat that Wyoming does, and that’s something to be proud of,” Ben Robb said. “Rather than just restoring a square mile, you would be practically doubling the access to the habitat, just by hopping a road.”

Across the Mountain West, it’s hard to imagine a bigger opportunity for restoration.
